Multivariate Statistical Methods

Assignment 3

Allan Gholmi, Emma Wallentinsson, Rasmus Holm 2017-12-15

Question 1

a)

The sample covariance matrix for the national tracks data is:

```
100m
         200m
                  400m
                           800m
                                   1500m
                                            3000m marathon
        1.0000000 0.9410886 0.8707802 0.8091758 0.7815510 0.7278784 0.6689597
100m
200m
        0.9410886 1.0000000 0.9088096 0.8198258 0.8013282 0.7318546 0.6799537
        0.8707802 0.9088096 1.0000000 0.8057904 0.7197996 0.6737991 0.6769384
400m
        0.8091758 0.8198258 0.8057904 1.0000000 0.9050509 0.8665732 0.8539900
800m
1500m
       0.7815510 0.8013282 0.7197996 0.9050509 1.0000000 0.9733801 0.7905565
        0.7278784 0.7318546 0.6737991 0.8665732 0.9733801 1.0000000 0.7987302
marathon 0.6689597 0.6799537 0.6769384 0.8539900 0.7905565 0.7987302 1.0000000
```

The eigenvalues are the following:

```
5.80762446\ 0.62869342\ 0.27933457\ 0.12455472\ 0.09097174\ 0.05451882\ 0.01430226
```

And the corresponding eigenvectors are (one vector per column):

b)

The first two principal components for the standardized variables is:

```
> princomp_1
[1] -0.3777657 -0.3832103 -0.3680361 -0.3947810 -0.3892610 -0.3760945 -0.3552031
> princomp_2
[1] -0.4071756 -0.4136291 -0.4593531 0.1612459 0.3090877 0.4231899 0.3892153
```

The cumulative percentage of the total sample variance explained by the two first principal components are 0.919474.

c)

The first component PC1, seems to have similar correlations to all of the variables, being aroundmeaning that the first principal component is moderately and negatively correlated with all variables. The second component PC2, are positively and moderately correlated with the first 3 variables which feels plausible since these 3 variables has a lower distance then the rest. The rest of the variables, are negatively and moderately correlate. PC1 might be called athletic excellence component and PC2 might be called distance component.

d)

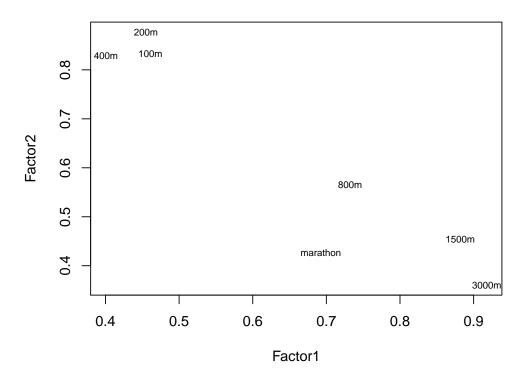

When we rank the scores of the different countries and check the countries with lowest scores, we recognize them from previous labs as countries who have bad results, e.g they have been outliers. The result makes sense.

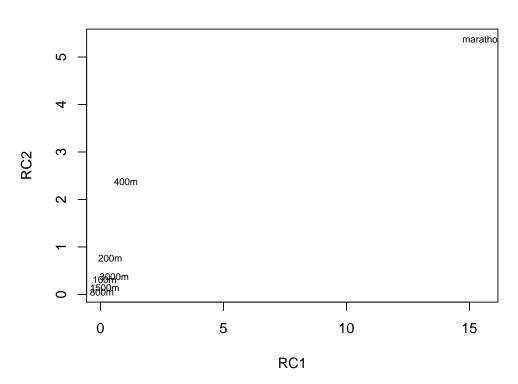

```
[,1] [,2]
[1,] "SAM" "-8.21341512287609"
[2,] "COK" "-7.90622722445813"
[3,] "PNG" "-5.25744974658153"
[4,] "GUA" "-3.29412379863809"
[5,] "SIN" "-3.09391951725173"
[6,] "DOM" "-2.19240980880379"
[7,] "CRC" "-2.16681150553093"
[8,] "PHI" "-1.76353368162812"
```

Question 2

```
library(psych)
data <- read.table("../data/T1-9.dat")</pre>
names(data) <- c("country", "100m", "200m", "400m", "800m", "1500m", "3000m", "marathon")</pre>
numeric_data <- data[, -1]</pre>
countries <- as.character(data$country)</pre>
S <- cov(numeric_data)
R <- cor(numeric_data)</pre>
factors <- 2
print(S)
#>
                100m
                          200m

#> 800m
           0.06137932
                       1.219655
#> 1500m
           0.21615514
                       3.539837
#> 3000m
           0.66475793 10.706091
#> marathon 10.70609113 270.270150
```

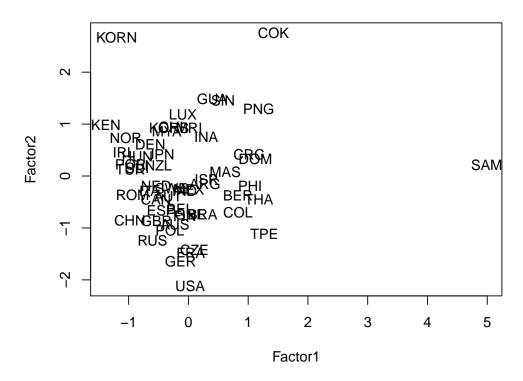

Since the data is measured in different units it is more appropriate to use the correlation matrix. We can see that the covariances of marathon is huge compared to the other variables which will pose a problem.

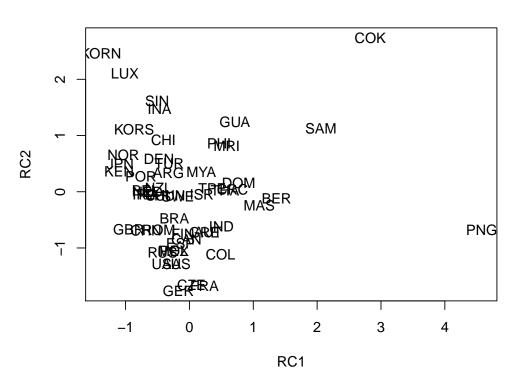

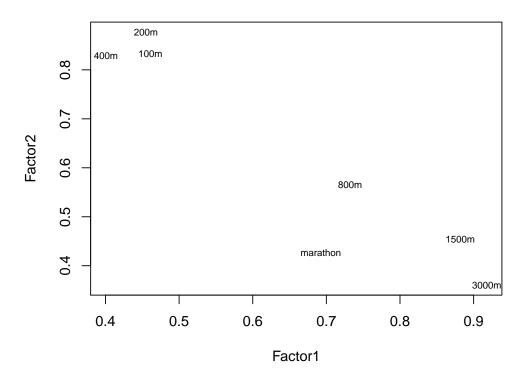

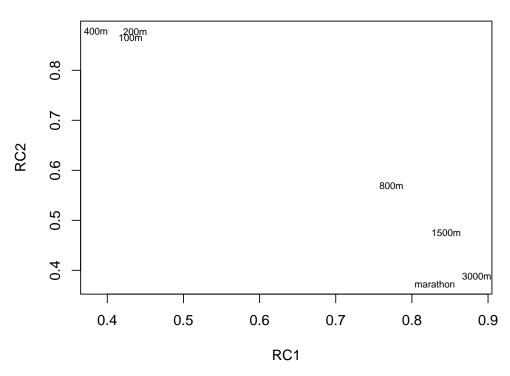

```

                     0.454
#> 3000m
            0.918
                     0.361
#>
  marathon 0.693
                     0.427
#>
#>
                   Factor1 Factor2
#> SS loadings
                             2.987
                     3.216
#> Proportion Var
                     0.459
                             0.427
#> Cumulative Var
                     0.459
                             0.886
```

We can see that the first principal component explains about 87% of the variance and the largest loading is associated with the marathon which is clear from the plot. The other component explains about 13% of the variance and is thus not very informative. These two components do not help us very much in understanding the nature of the data because we did not normalize the data.

                     0.427
#>
#>
                   Factor1 Factor2
#> SS loadings
                             2.987
                     3.216
#> Proportion Var
                     0.459
                             0.427
#> Cumulative Var
                     0.459
                             0.886
```

Now the first two principal components explains about the same amount of variance and in total almost 92% so its a decent fit. Similar values are true for the factors and so the two solutions give similar results. The first factor/principal component seem to represent shorter races since those load highly on it and the other represent longer races, but the opposite loadings are still rather high. So these factors could be interpreted as representing speed versus endurance.

We can see from the plots that the factor and principal component scores indicate that North Korea, Cook Islands, Samoa, and Papua New Guinea are outliers.

Setting rotation to varimax means that the algorithm rotates the loadings such as to maximize their variances. As a result of this rotation, each variable loads more heavily on a single factor making the factors easier to interpret.

Appendix

Code

```
## Question 1
data<- read.table("T1-9.dat")</pre>
rownames(data)<- data[,1]</pre>
data<- data[,-1]</pre>
colnames(data) <- c("100m","200m","400m","800m","1500m","3000m","marathon")
