Multivariate Statistical Methods

Assignment 3

Allan Gholmi, Emma Wallentinsson, Rasmus Holm 2017-12-14

Question 2

```
library(psych)

data <- read.table("../data/T1-9.dat")
names(data) <- c("country", "100m", "200m", "400m", "800m", "1500m", "3000m", "marathon")
numeric_data <- data[, -1]
countries <- as.character(data$country)

S <- cov(numeric_data)
R <- cor(numeric_data)
factors <- 2</pre>
```

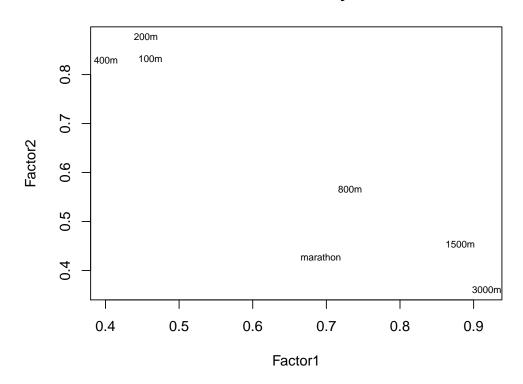

Since the data is measured in different units it is more appropriate to use the correlation matrix.

Analysis on Covariance Matrix

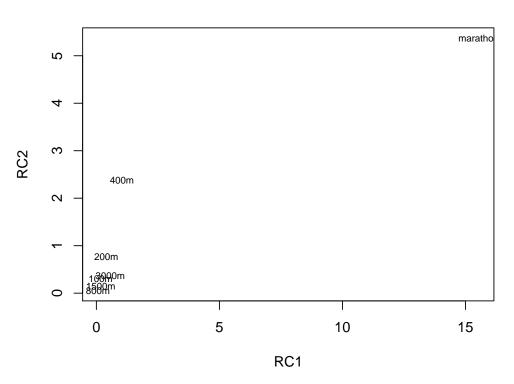

```
S_principal <- principal(S, factors, rotate="varimax", covar=TRUE)
S_factanalysis <- factanal(numeric_data, factors=factors, covmat=S, rotation="varimax")
S_factoranalysis_loadings <- S_factanalysis$loadings[, 1:2]
S_principal_loadings <- S_principal$loadings[, 1:2]

old <- par(mfrow=c(2, 1))
plot(S_factoranalysis_loadings, type="n", main="ML Factor Analysis")
text(S_factoranalysis_loadings, labels=names(numeric_data), cex=.7)

plot(S_principal_loadings, type="n", main="PCA")
text(S_principal_loadings, labels=names(numeric_data), cex=.7)</pre>
```

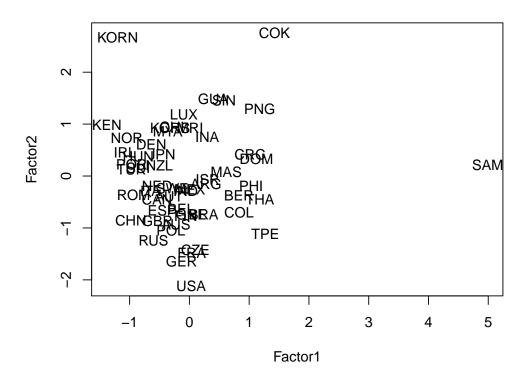

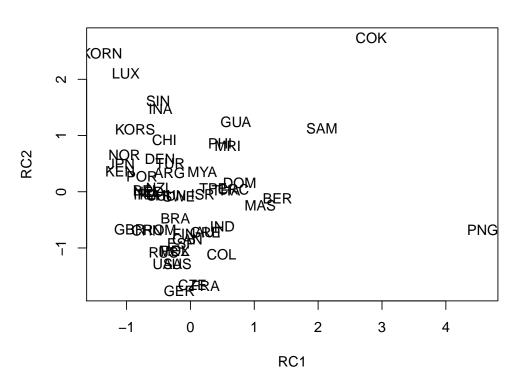

par(old)

```
print("PCA")
 #> [1] "PCA"
S_principal$Vaccounted
                                                                                                                                           RC1
                                                                                                                                                                                          RC2

 #> SS loadings
                                                                                    3.216 2.987
#> Proportion Var
                                                                                    0.459 0.427
#> Cumulative Var
                                                                                    0.459
                                                                                                                      0.886
```

We can see that the first principal component explains about 87% of the variance and the largest loading is associated with the marathon which is clear from the plot.

PCA

```
par(old)
```

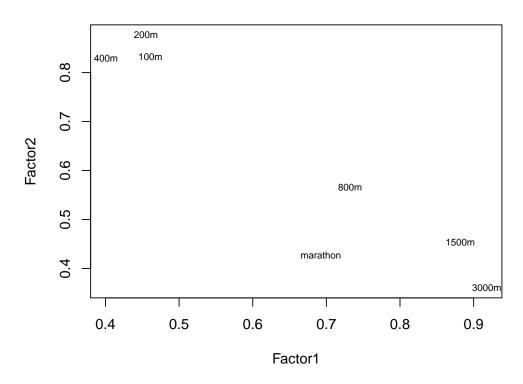

Analysis on Correlation Matrix

```
R_principal <- principal(R, factors, rotate="varimax", covar=FALSE)
R_factanalysis <- factanal(numeric_data, factors=factors, covmat=R, rotation="varimax")

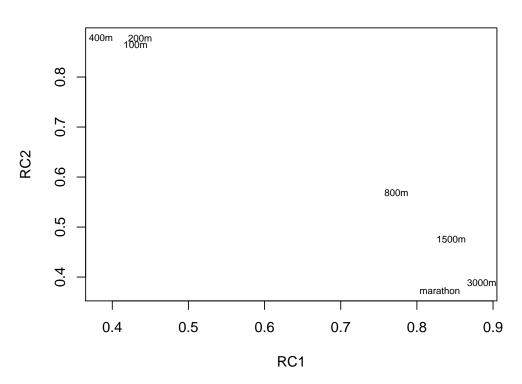

R_factoranalysis_loadings <- R_factanalysis$loadings[, 1:2]
R_principal_loadings <- R_principal$loadings[, 1:2]

old <- par(mfrow=c(2, 1))
plot(R_factoranalysis_loadings, type="n", main="ML Factor Analysis")
text(R_factoranalysis_loadings, labels=names(numeric_data), cex=.7)

plot(R_principal_loadings, type="n", main="PCA")
text(R_principal_loadings, labels=names(numeric_data), cex=.7)</pre>
```

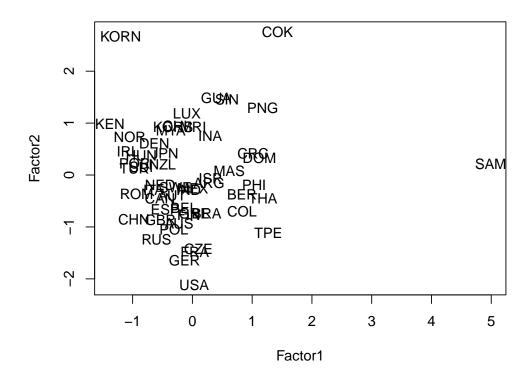

PCA

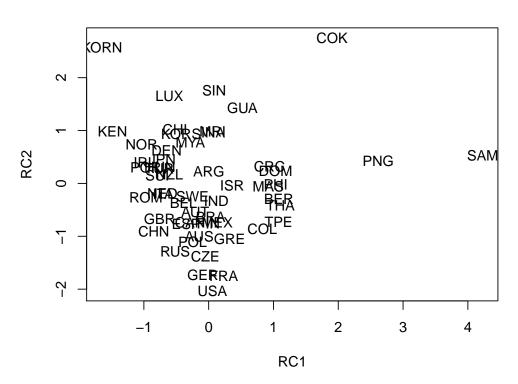

par(old)

```
print("PCA")
#> [1] "PCA"
R_principal$Vaccounted
                            RC1
                                      RC2
                       3.3087124 3.1276055

                  0.459 0.427
#> Cumulative Var
                  0.459
                          0.886
```

Now the first two principal components explains about the same amount of variance and in total almost 92% so its a pretty good fit. Similar values are true for the factors.

PCA

par(old)

Setting rotation to varimax means that the algorithm rotates the loadings such as to maximize their variances. As a result of this rotation, each variable loads more heavily on a single factor making the factors easier to interpret.

Appendix
